Introduction

Feature selection is important for handling high-dimensional data:

- User data \((d > 100)\)
  e.g., e-mail spam detection.
- Gene expression data \((d > 20000)\)
  e.g., cancer classification.
- Text based feature such as TF-IDF \((d > 100,000)\)
  e.g., Sentiment analysis
The purpose of feature selection is

- to improve the prediction accuracy by getting rid of non-important features.
- to make the prediction faster.
- to interpret data.
- to handle high-dimensional data.
Let us think about a least-squared regression problem:

$$
\min_{w \in \mathbb{R}^d} \| y - X^T w \|_2^2
$$

where \( x = (x_1, x_2, \ldots, x_d)^\top \in \mathbb{R}^d \), \( X = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^{d \times n} \), \( w = (w_1, w_2, \ldots, w_d)^\top \in \mathbb{R}^d \), \( y \in \mathbb{R}^n \), and \( \| \cdot \|_2^2 \) is the \( \ell_2 \) norm.

Question:

- \( d < n \) and the rank of \( X \) is \( d \). Please derive the analytical solution of \( w \).
Take the objective function with respect to $w$ and set it to zero:

$$\frac{\partial}{\partial w} \| y - X^\top w \|_2^2 = -2X(y - X^\top w) = 0$$

Use Eq. (84) of [1]. The solution is given as

$$\hat{w} = (XX^\top)^{-1}Xy.$$ 

If the rank of $X$ is $d$, the rank of $XX^\top$ is also $d$ and it is invertible.

What happens if the rank of $X$ is less than $d$?

- $XX^\top$ is not invertible.
- Maybe, we can add a regularizer (or use pseudo-inverse). we get a dense solution and numerically unstable :(

A possible solution is to use feature selection! If we select $r < d$ features, we can compute $w$. 
Problem formulation of feature selection

- Input vector: \( \mathbf{x} = (x_1, x_2, \ldots, x_d)^\top \in \mathbb{R}^d \)
- Output: \( y \in \mathbb{R} \)
- Paired data: \( \{(\mathbf{x}_i, y_i)\}_{i=1}^n \)

**Goal:** Select \( r \) \((r < d)\) features of input \( \mathbf{x} \) that are responsible for output \( y \).

**Problems:** There is \( 2^d \) combinations :(! It is hard even if \( d \) is 100.)
The feature selection algorithms are categorized into three types:

- **Wrapper Method**
  Use a predictive model to select features.

- **Filter Method**
  Use a proxy measure (such as mutual information) instead of the error rate to select features.

- **Embedded Method**
  Features are selected as part of the model construction process.
Wrapper Method

Use a predictive model (e.g., classifier) to select features.

The simplest approach would be...

1. Generate feature set $S_t$
2. Train predictive model with $S_t$ and test the prediction accuracy with hold-out set.
3. Iterate 1 and 2 until all feature combination is examined.
Wrapper Method

Pro:
- It can select features that have feature-feature interaction.

Cons:
- It can be overfitted if the number of samples is insufficient.
- Computationally expensive.

Wrapper method is not that popular compared to filter and embedded methods...

\[ \{ (x_i, y_i) \}_{i=1}^{n} \]

Generate feature set

Evaluate the model with validation set

Train classifier/regressor
Filter Method

Use a proxy measure (such as mutual information) instead of the error rate to select features.

Pros:
- Easy to implement.
- It scales well (easy to implement with distributed computing).
- Can select features from high-dimensional data (both linear and nonlinear way).

Cons:
- The feature selection is independent of the model. The selected features may not be the best set to achieve highest accuracy.
- It is hard to detect select features with interaction. (Of course, we can somehow select them, but it increase computation cost.)
Filter Method (Example)

**Maximum Relevance Feature Selection (MR)**
Compute association score between each feature and its output and rank them.
- Correlation, Mutual information, and the kernel based independence measures are used.
- Easy to implement and it scales well.

**Optimization problem:**

\[
\max_{\beta \in \{0,1\}^d} \frac{1}{S} \sum_{k=1}^d \beta_k I(X_k, Y),
\]

where \( S = \beta_1 + \ldots + \beta_d \).
Filter Method (Example)

Minimum Redundancy Maximum Relevance (mRMR) [2]
MR feature selection tends to select redundant features.

mRMR method is to
- select features that have high association to its output.
- select independent features.

Optimization problem:

\[ \max_{\beta \in \{0,1\}^d} \frac{1}{S} \sum_{k=1}^{d} \beta_k I(X_k, Y) - \frac{1}{S^2} \sum_{k=1}^{d} \sum_{k'=1}^{d} \beta_k \beta_{k'} I(X_k, X_{k'}). \]

This optimization problem can be solved by using greedy algorithm.
Filter Method (Mutual Information)

To optimize mRMR, we tend to use the **mutual information** as an association score.

**Independence:**

\[ p(x, y) = p(x)p(y) \]

**Mutual Information:**

\[
\text{MI}(X, Y) = \int \int p(x, y) \log \frac{p(x, y)}{p(x)p(y)} \, dx \, dy
\]

Under independence:

\[
\text{MI}(X, Y) = \int \int p(x, y) \log \frac{p(x)p(y)}{p(x)p(y)} \, dx \, dy = 0
\]
Filter Method (Linear Correlation)

To optimize mRMR, we may be able to use the Pearson’s correlation coefficient

Pearson’s correlation coefficient:

\[
PCC(X, Y) = \frac{\text{Cov}(X, Y)}{\sigma_X \sigma_Y},
\]

\[
\text{Cov}(X, Y) = \mathbb{E}[(X - \mu_X)(Y - \mu_Y)]
\]

where \( \mu_X = \mathbb{E}[X] \) is the mean of \( X \), \( \mu_Y = \mathbb{E}[Y] \) is the mean of \( Y \), \( \sigma_X^2 = \mathbb{E}[(X - \mu_X)^2] \) is the variance of \( X \), and \( \sigma_Y^2 = \mathbb{E}[(Y - \mu_Y)^2] \) is the variance of \( Y \). (\( \sigma_X \) and \( \sigma_Y \) are the standard deviations.)

The covariance can be written as

\[
\text{Cov}(X, Y) = \mathbb{E}[(X - \mu_X)(Y - \mu_Y)] = \mathbb{E}[XY] - \mathbb{E}[X] \mathbb{E}[Y].
\]

That is, if \( PCC(X, Y) = 0 \), \( \mathbb{E}[XY] = \mathbb{E}[X] \mathbb{E}[Y] \)
The relationship between independence and correlation

If $X$ and $Y$ are independent, we can write

$$\mathbb{E}[XY] = \int\int xy \ p(x, y) \, dx \, dy,$$

$$= \int\int xy \ p(x)p(y) \, dx \, dy, \quad \text{(independence)}$$

$$= \left( \int x \ p(x) \, dx \right) \left( \int y \ p(y) \, dy \right)$$

$$= \mathbb{E}[X] \mathbb{E}[Y]$$

That is, if $X$ and $Y$ are independent, $\mathbb{E}[XY] = \mathbb{E}[X] \mathbb{E}[Y]$. Note that, even if $\mathbb{E}[XY] = \mathbb{E}[X] \mathbb{E}[Y]$, $X$ and $Y$ can be dependent.
Empirical estimation of covariance

To optimize mRMR, we may be able to use the Pearson’s correlation coefficient

Covariance (population):

\[
\text{Cov}(X, Y) = \mathbb{E}[(X - \mu_X)(Y - \mu_Y)]
\]

Covariance estimation:

\[
\hat{\text{Cov}}(X, Y) = \frac{1}{n} \sum_{i=1}^{n} (x_i - \hat{\mu}_X)(y_i - \hat{\mu}_Y)
\]

\[
\hat{\mu}_X = \frac{1}{n} \sum_{i=1}^{n} x_i = \frac{1}{n} x^\top 1_n, \quad \hat{\mu}_Y = \frac{1}{n} \sum_{i=1}^{n} y_i = \frac{1}{n} y^\top 1_n,
\]

where \(1_n = (1, 1, \ldots, 1)^\top \in \mathbb{R}^n\) is the vector with all ones.
Empirical estimation of covariance

Covariance estimation:

\[
\hat{\text{Cov}}(X, Y) = \frac{1}{n} \sum_{i=1}^{n} (x_i - \frac{1}{n} \mathbf{x}^\top \mathbf{1}_n)(y_i - \frac{1}{n} \mathbf{y}^\top \mathbf{1}_n)
\]

\[
= \frac{1}{n} \left( \sum_{i=1}^{n} x_i y_i - \frac{1}{n} \mathbf{x}^\top \mathbf{1}_n \mathbf{1}_n^\top \mathbf{y} \right)
\]

\[
= \frac{1}{n} \left( \mathbf{x}^\top \mathbf{y} - \frac{1}{n} \mathbf{x}^\top \mathbf{1}_n \mathbf{1}_n^\top \mathbf{y} \right)
\]

\[
= \frac{1}{n} \mathbf{x}^\top \left( \mathbf{I}_n - \frac{1}{n} \mathbf{1}_n \mathbf{1}_n^\top \right) \mathbf{y}
\]

\[
= \frac{1}{n} \mathbf{x}^\top \mathbf{H} \mathbf{y},
\]

where \( \mathbf{H} = \mathbf{I}_n - \frac{1}{n} \mathbf{1}_n \mathbf{1}_n^\top \) is the centering matrix and \( \mathbf{I}_n \) is the identity matrix. \( \text{(Note } \mathbf{HH} = \mathbf{H} \text{).} \)
Empirical estimation of covariance

Covariance estimation:

\[
\hat{\text{Cov}}(X, Y)^2 = \frac{1}{n^2} x^\top H y x^\top H y,
\]

\[
= \frac{1}{n^2} \text{tr} \left( x^\top H y y^\top H x \right)
\]

\[
= \frac{1}{n^2} \text{tr} \left( x x^\top H y y^\top H \right)
\]

\[
= \frac{1}{n^2} \text{tr} (K H L H),
\]

where \( K = x x^\top \in \mathbb{R}^{n \times n} \) and \( L = y y^\top \in \mathbb{R}^{n \times n} \).
Hilbert Schmidt Independence Criterion (HSIC) [3]

Empirical V-statistics of HSIC is given as

\[
\text{HSIC}(X, Y) = \frac{1}{n^2} \text{tr}(KH \Psi \Phi^T \Psi H)
\]

where we use the Gaussian kernel:

\[
K_{ij} = \exp \left( -\frac{\|x_i - x_j\|^2}{2\sigma^2} \right), \quad L_{ij} = \exp \left( -\frac{\|y_i - y_j\|^2}{2\sigma^2} \right).
\]

HSIC takes 0 if and only if \(X\) and \(Y\) are independent.

Since we can decompose \(K = \Phi^T \Phi\) and \(L = \Psi^T \Psi\), we have

\[
\text{HSIC}(X, Y) = \frac{1}{n^2} \text{tr}(\Phi^T \Phi H \Psi^T \Psi H) = \frac{1}{n^2} \|\text{vec}(\Psi H \Phi^T)\|_2^2 \geq 0
\]

We can use the normalized variant of HSIC (takes 0 to 1) [4]:

\[
\text{NHSIC}(X, Y) = \text{tr}(\tilde{K} \tilde{L}), \quad \tilde{K} = \frac{HKH}{\|HKH\|_F}, \quad \tilde{L} = \frac{HLH}{\|HLH\|_F}
\]
Hilbert-Schmidt Independence Criterion (HSIC) experiments

- X and Y are independent
  - NHSIC = 0.0031
  - Pearson CC = 0.0343

- X and Y are dependent
  - NHSIC = 0.2842
  - Pearson CC = 0.1983

Makoto Yamada
myamada@i.kyoto-u.ac.jp
(Kyoto University)
Filter Method (Continuous optimization)

The MR and mRMR feature selection algorithms are discrete optimization problem. In feature selection, continuous optimization based approach is also popular.

The key idea is to relax the condition (i.e., allow to take continuous number).

**Quadratic Programming Feature Selection (QPFS)** [5]:

\[
\max_{\alpha \in \mathbb{R}^d} \sum_{k=1}^{d} \alpha_k l(X_k, Y) - \frac{1}{2} \sum_{k=1}^{d} \sum_{k'=1}^{d} \alpha_k \alpha_{k'} l(X_k, X_{k'}),
\]

s.t. \( \alpha_1 + \alpha_2 + \ldots + \alpha_d = 1, \ \alpha_1, \ldots, \alpha_d \geq 0 \)
Filter Method (Continuous optimization)

Let us denote:

\[ h_k = I(X_k, Y), \]
\[ H_{kk'} = I(X_k, X_{k'}) \]

where \( h \in \mathbb{R}^d \) and \( H \in \mathbb{R}^{d \times d} \).

We have

\[
\min_{\alpha \in \mathbb{R}^d} \frac{1}{2} \alpha^\top H \alpha - h^\top \alpha \\
\text{s.t. } \alpha^\top 1 = 1, \alpha_1, \ldots, \alpha_d \geq 0.
\]

This is a quadratic programming with simplex constraint (can be solved by using an off-the-shelf package).

Note: For mutual information, \( H \) may not be positive definite. It can be non-convex optimization.
Embedded Method

Features are selected as part of the model construction process. Embedded method can be regarded as an intermediate method between wrapper and filter methods.

Pros:
- Can select features with high prediction accuracy.
- Computationally efficient than wrapper method.

Cons:
- Computationally expensive than filter method.
- If the input output relationship are nonlinear, it is computationally expensive. It is more suited for linear method.
Embedded Method (Lasso)

Least Absolute Shrinkage and Selection Operator (Lasso)

The optimization problem of Lasso can be written as

$$\min_w \frac{1}{2} \| y - X^\top w \|_2^2 + \lambda \| w \|_1,$$

where $X = (x_1, \ldots, x_n) \in \mathbb{R}^{d \times n}$ is the input matrix and $y = (y_1, \ldots, y_n)^\top \in \mathbb{R}^n$ is the output vector.

$$\| w \|_1 = \sum_{k=1}^d |w_k|$$

is an $\ell_1$ norm.

Lasso is a convex method: The first term is a convex function w.r.t. $w$. $\ell_1$ norm (all norm) is convex:

$$\| \alpha w + (1 - \alpha) v \|_1 \leq \| \alpha w \|_1 + \| (1 - \alpha) v \|_1$$  \hspace{1cm} (triangle inequality)

$$= \alpha \| w \|_1 + (1 - \alpha) \| v \|_1$$  \hspace{1cm} (absolutely scalable),

where $0 \leq \alpha \leq 1$. The sum of two convex functions is convex.
Using the $\ell_1$ regularizer, we can make $\mathbf{w}$ sparse. The $\ell_1$ regularization is equivalent to $\ell_1$ norm constraint:

$$\min_{\mathbf{w}} f(\mathbf{w}) + \lambda \|\mathbf{w}\|_1 \rightarrow \min_{\mathbf{w}} f(\mathbf{w}), \text{ s.t. } \|\mathbf{w}\|_1 \leq \eta.$$ 

If we consider the Lagrange function of the $\ell_1$ norm constraint, there exists the same solution of the $\ell_1$ norm constraint with an arbitrary $\lambda$.

Level curves of norms and loss:

\[ f(\mathbf{w}) = C \]

\[ \|\mathbf{w}\|_2 = 1 \]

\[ \|\mathbf{w}\|_1 = 1 \]
Let us think about a least-squared regression problems:

\[
\min_{\mathbf{w} \in \mathbb{R}^d} \| \mathbf{y} - \mathbf{X}^\top \mathbf{w} \|^2_2
\]

where \( \mathbf{x} = (x_1, x_2, \ldots, x_d)^\top \in \mathbb{R}^d \) and \( \mathbf{y} \in \mathbb{R}^n \), and \( \| \cdot \|^2_2 \) is the \( \ell_2 \) norm.

Take the objective function with respect to \( \mathbf{w} \) and set it to zero:

\[
\frac{\partial}{\partial \mathbf{w}} \| \mathbf{y} - \mathbf{X}^\top \mathbf{w} \|^2_2 = -2\mathbf{X}(\mathbf{y} - \mathbf{X}^\top \mathbf{w}) = 0
\]

Use Eq. (84) of [1]. The solution is given as

\[
\hat{\mathbf{w}} = (\mathbf{X}\mathbf{X}^\top)^{-1}\mathbf{X}\mathbf{y}.
\]

If the rank of \( \mathbf{X} \) is \( d \), the rank of \( \mathbf{X}\mathbf{X}^\top \) is also \( d \) and it is invertible.

What happens if the rank of \( \mathbf{X} \) is less than \( d \)?

- \( \mathbf{X}\mathbf{X}^\top \) is not invertible \( \rightarrow \) Adding \( \ell_1 \) regularizer to make \( \mathbf{w} \) sparse
- The number of nonzero elements of \( \mathbf{w} \) should be smaller than \( n \).
Embedded Method (Lasso)

Lasso has no closed form solution. Thus, we need to iteratively optimize the problem.

Here, we introduce the Alternating Direction Method of Multipliers (ADMM) [6].

We can rewrite the Lasso optimization problem as

$$\min_{w, z} \frac{1}{2} \| y - X^T w \|_2^2 + \lambda \| z \|_1 + \frac{\rho}{2} \| w - z \|_2^2$$

s.t. \( w = z \)

The key idea here is to split the main objective and the non-differentiable regularization term. Since the last term \( \frac{\rho}{2} \| w - z \|_2^2 \) is zero if the constraint is satisfied, this problem is equivalent to the original Lasso problem.
Embedded Method (Lasso)

Let us denote the Lagrange multipliers as $\gamma \in \mathbb{R}^d$, we can write a Lagrangian function (called Augmented Lagrangian function) as follows:

$$
J(w, z, \gamma) = \frac{1}{2} \| y - X^T w \|^2_2 + \gamma^T (w - z) + \lambda \| z \|_1 + \frac{\rho}{2} \| w - z \|^2_2,
$$

where $\rho > 0$ is a tuning parameter.

In ADMM, we consider the following optimization problem:

$$
\max_{\gamma} \min_{w, z} J(w, z, \gamma) = \frac{1}{2} \| y - X^T w \|^2_2 + \gamma^T (w - z) + \lambda \| z \|_1 + \frac{\rho}{2} \| w - z \|^2_2,
$$

Since we have the relationship,

$$
\max_{\gamma} J(w, z, \gamma) = \left\{ \begin{array}{ll}
\frac{1}{2} \| y - X^T w \|^2_2 + \lambda \| z \|_1 & (w = z) \\
\infty & \text{(Otherwise)}
\end{array} \right.
$$

The optimization problem is equivalent to the original Lasso problem.
Embedded Method (Lasso)

Minimizing $J(w, z, \gamma)$ w.r.t. $w$. If we fix $z$ and $\gamma$ as $z^{(t)}$ and $\gamma^{(t)}$, $J(w, z^{(t)}, \gamma^{(t)})$ is convex w.r.t. $w$. That is,

$$\frac{\partial J(w, z, \gamma)}{\partial w} = -X(y - X^\top w) + \gamma + \rho(w - z) = 0.$$  

Here, we can use the following equation (see [1] Eq. (84)):

$$\frac{\partial \|y - X^\top w\|^2_2}{\partial w} = -2X(y - X^\top w).$$

Solving it for $w$:

$$(XX^\top + \rho I)w = XY - \gamma^{(t)} + \rho z^{(t)}$$

$$w^{(t+1)} = (XX^\top + \rho I)^{-1}(XY - \gamma^{(t)} + \rho z^{(t)}).$$
Minimizing $J(w, z, \gamma)$ w.r.t. $z$. If we fix $w$ and $\gamma$ as $w^{(t)}$ and $\gamma^{(t)}$, $J(w^{(t)}, z, \gamma^{(t)})$ is convex w.r.t. $z$.

$$J(w^{(t)}, z, \gamma^{(t)}) = \frac{\rho}{2} ||z - w^{(t)}||_2^2 + \lambda ||z||_1 - \gamma^\top z + \text{Const.}$$

$||z||_1$ is not differentiable at 0. However, we can analytically solve the problem! Moreover, since there is no interaction in the elements of $z$, we can solve it for each element.

$$J(w^{(t)}, (z_1, \ldots, z_\ell, \ldots, z_d), \gamma^{(t)}) = \frac{\rho}{2} (z_\ell - w_\ell^{(t)})^2 + \lambda |z_\ell| - \gamma_\ell z_\ell + \text{Const.}$$
$J(w^{(t)}, (z_1, \ldots, z_\ell, \ldots, z_d), \gamma^{(t)}) = \frac{\rho}{2}(z_\ell - w^{(t)}_\ell)^2 + \lambda |z_\ell| - \gamma_\ell z_\ell + \text{Const}.$

Case 1: $z_\ell > 0$, $\rho(z_\ell - w^{(t)}_\ell) + \lambda - \gamma_\ell = 0 \rightarrow z_\ell = w^{(t)}_\ell + \frac{1}{\rho}(\gamma_\ell - \lambda)$
That is, $z_\ell > 0$ if $w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell > \frac{\lambda}{\rho}$

Case 2: $z_\ell < 0$, $\rho(z_\ell - w^{(t)}_\ell) - \lambda - \gamma_\ell = 0 \rightarrow z_\ell = w^{(t)}_\ell + \frac{1}{\rho}(\gamma_\ell + \lambda)$
That is, $z_\ell < 0$ if $w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell < -\frac{\lambda}{\rho}$

Case 3: $z_\ell = 0$, $0 \in \rho(z_\ell - w^{(t)}_\ell) + \lambda[-1 1] - \gamma_\ell \rightarrow w_\ell + \frac{1}{\rho} \gamma_\ell \in [\frac{-\lambda}{\rho}, \frac{\lambda}{\rho}],$ ($z_\ell = 0$).

Therefore, we have

$$z_\ell = \begin{cases} 
    w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell - \frac{\lambda}{\rho} & (w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell > \frac{\lambda}{\rho}) \\
    0 & (w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell \in [\frac{-\lambda}{\rho}, \frac{\lambda}{\rho}]) \\
    w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell + \frac{\lambda}{\rho} & (w^{(t)}_\ell + \frac{1}{\rho} \gamma_\ell < -\frac{\lambda}{\rho})
\end{cases}$$
Let us introduce the **Soft-Thresholding function**:

\[
S_\lambda(x) = \begin{cases} 
  x - \lambda & (x > \lambda) \\
  0 & (x \in [-\lambda, \lambda]) \\
  x + \lambda & (x < -\lambda)
\end{cases},
\]

\[
= \text{sign}(x) \max(0, |x| - \lambda)
\]

Therefore, the update of \( z_\ell \) can be simply written by the soft-thresholding function as

\[
\hat{z}_\ell^{(t+1)} = S_{\frac{\lambda}{\rho}} \left( w_\ell^{(t)} + \frac{1}{\rho} \gamma_\ell \right).
\]
Maximizing $J(w, z, \gamma)$ w.r.t. $\gamma$. That is the optimization problem can be written as

$$\max_{\gamma} J(w, z, \gamma) = \gamma^\top (w - z).$$

To optimize this problem, since we cannot get the analytical solution, we use the gradient ascent algorithm:

$$\gamma^{(t+1)} = \gamma^{(t)} + \rho (w^{(t)} - z^{(t)}).$$

Thus, the ADMM algorithm for Lasso can be summarized as

$$w^{(t+1)} = (XX^\top + \rho I)^{-1}(XY - \gamma^{(t)} + \rho z^{(t)})$$

$$z_{\ell}^{(t+1)} = \frac{1}{\rho}(w^{(t+1)} + \frac{1}{\rho} \gamma)$$

$$\gamma^{(t+1)} = \gamma^{(t+1)} + \rho (w^{(t+1)} - z^{(t+1)}).$$
Embedded Method (Elastic-Net)

For Lasso, the number of non-zero features should be smaller than $n$.

**How to select $r > n$ variables?**

**Ans:** Use the elastic net regularization [7]:

$$\min_w \|y - X^T w\|^2_2 + \lambda (\alpha \|w\|_1 + (1 - \alpha) \|w\|^2_2),$$

where $0 \leq \alpha \leq 1$ and $\lambda > 0$ is a regularization parameter.

$\|w\|^2_2$ is differentiable; we can similarly solve it with ADMM.

$$w^{(t+1)} = (XX^T + 2\lambda(1 - \alpha)I + \rho I)^{-1}(XY - \gamma^{(t)} + \rho z^{(t)})$$

$$z_{\ell}^{(t+1)} = S_{\frac{\lambda\alpha}{\rho}} (w^{(t+1)} + \frac{1}{\rho} \gamma)$$

$$\gamma^{(t+1)} = \gamma^{(t+1)} + \rho (w^{(t+1)} - z^{(t+1)}).$$

Thanks to the $\ell_2$ regularization, $w$ tends to be dense.
Minimum Redundancy Maximum Relevance (mRMR) [2]
MR feature selection tends to select redundant features.
mRMR method is to

- select features that have high association to its output.
- select independent features.

Optimization problem:

$$\max_{\beta \in \{0, 1\}^d} \frac{1}{S} \sum_{k=1}^{d} \beta_k I(X_k, Y) - \frac{1}{S^2} \sum_{k=1}^{d} \sum_{k'=1}^{d} \beta_k \beta_{k'} I(X_k, X_{k'})$$

This optimization problem can be solved by using greedy algorithm.
Advanced Topic (HSIC Lasso)

- Convex variant of mRMR (can obtain a globally optimal solution.
- Key idea: Use NHSIC instead of MI

\[
\text{NHSIC}(Y, Y) - \sum_{k=1}^{d} \alpha_k \text{NHSIC}(X_k, Y) + \frac{1}{2} \sum_{k,k'=1}^{d} \alpha_k \alpha_{k'} \text{NHSIC}(X_k, X_{k'})
\]

- NHSIC can be decomposed as

\[
\text{NHSIC}(X, Y) = \text{tr}(\bar{K}\bar{L}) = \text{vec}(\bar{K})^\top \text{vec}(\bar{L}).
\]

\[
\begin{align*}
\text{vec}(\bar{L})^\top \text{vec}(\bar{L}) - \sum_{k=1}^{d} \alpha_k \text{vec}(\bar{K}^{(k)})^\top \text{vec}(\bar{L}) + \frac{1}{2} \sum_{k,k'=1}^{d} \alpha_k \alpha_{k'} \text{vec}(\bar{K}^{(k)})^\top \text{vec}(\bar{K}^{(k')}) \\
= \|\text{vec}(\bar{L}) - \sum_{k=1}^{d} \alpha_k \text{vec}(\bar{K}^{(k)})\|^2 \\
= \|\bar{L} - \sum_{k=1}^{d} \alpha_k \bar{K}^{(k)}\|_F^2 \quad \text{(Convex w.r.t. } \alpha)\]
\]
Advanced Topic (HSIC Lasso)

Hilbert Schmidt Independence Criterion Lasso (HSIC Lasso) [8]

\[
\min_{\alpha} \frac{1}{2} \| \bar{L} - \sum_{k=1}^{d} \alpha_k \bar{K}^{(k)} \|_F^2 + \lambda \| \alpha \|_1, \quad \text{s.t.} \quad \alpha_1, \ldots, \alpha_d \geq 0
\]

Since the number of selected features is much smaller than that of \(d\), \(\beta\) in mRMR is sparse. Thus, using \(\ell_1\) regularization to \(\alpha\) is a natural choice.

- \(\bar{K}^{(k)} \in \mathbb{R}^{n \times n}\): Gram matrix of the \(k\)-th feature.
- \(\bar{L} \in \mathbb{R}^{n \times n}\): Gram matrix of output.
- The loss function is convex; it can find a globally optimal solution!
- If \(d \gg n(n - 1)/2\), it is memory efficient.
- Can be easily solved by non-negative Lasso

\[
\min_{\alpha} \| \text{vec}(\bar{L}) - \sum_{k=1}^{d} \alpha_k \text{vec}(\bar{K}^{(k)}) \|_2^2 + \lambda \| \alpha \|_1, \quad \text{s.t.} \quad \alpha_1, \ldots, \alpha_d \geq 0
\]
Feature selection: Wrapper method, Filter method, and Embedded method

Wrapper method (Selecting features that maximize prediction accuracy. Computationally expensive.)

Filter method (Use mutual information to select features, e.g., MR, mRMR, QPFS, etc.)

Embedded method (Selecting features during training. e.g., Lasso)

Alternating Direction Method of Multipliers (ADMM).
